Chemical precipitation and characterization of multicomponent Perovskite Oxide nanoparticles – possible cathode materials for low temperature solid Oxide fuel cell

ABSTRACT

A set of multicomponent perovskite oxide nanoparticles based on \( \text{La}_{1-x}\text{Sr}_x\text{Co}_{1-y}\text{Fe}_y\text{O}_{3-\delta} \) (LSCF) were prepared by a simple chemical precipitation method for application in low temperature solid oxide fuel cells (LT-SOFC) as cathode materials. The precursor materials used in this synthesis were lanthanum nitrate hexahydrate \( \text{La(NO}_3\text{)}_3\cdot6\text{H}_2\text{O} \), strontium nitrate \( \text{Sr(NO}_3\text{)}_2 \), cobalt nitrate hexahydrate \( \text{Co(NO}_3\text{)}_2\cdot6\text{H}_2\text{O} \), ferric nitrate nonahydrate \( \text{Fe(NO}_3\text{)}_3\cdot9\text{H}_2\text{O} \) [as basic materials] and sodium hydroxide [as precipitator material] and PVA [as surfactant]. Throughout the experiment, pH was maintained as pH > 9 by the addition of alkali (NaOH). A mixture of metal hydroxides (brown coloured) was formed when the aqueous mixture of basic materials mixed with the aqueous precipitant (NaOH) solution in proper stoichiometric compositions. The resultant hydroxide mixture was washed with ethanol and water mixture (1:9 volume %) to remove any unwanted impurities present along with the precipitate. The purified precipitate was dried at 50 – 100°C and heat treated at 300°C, 450°C, 600°C and 750°C for 2 hours each to get phase pure composite oxide powder. The resultant powder was characterized with TGA / DTA, XRD, FT-IR, Particle Size analysis and SEM. From the results, it was found that the chemical precipitation can be used effectively to prepare phase pure multicomponent perovskite oxides for application in SOFCs.

Keywords: Chemical precipitation, Multicomponent Perovskite Oxide nanoparticles, Cathode materials, SOFC.

INTRODUCTION

One of the driving forces behind the research effort directed towards SOFC technology is a lowering of the operating temperature of the fuel cell from 1000°C to around 600°C (low temperature range). However, to enable this, new materials with good lower-temperature performance in terms of level of conductivity, chemical and mechanical compatibility have to be identified and developed.
Manganite based perovskite oxides such as La$_{1-x}$Sr$_x$MnO$_{3-δ}$ (LSM) have been widely used as cathodes due to their stability at high temperatures and thermal expansion compatibility with yttria stabilized zirconia (YSZ). These manganite based perovskites have relatively good stability at high temperature; however during long annealing times, pyrochlores (La$_2$Zr$_2$O$_7$) are reported to form at the boundary between LSM and YSZ [1-2]. Better electrode materials that are less reactive with adjoining electrolyte are required. Moreover, to reduce the operating temperature of the SOFCs, a search for new cathode materials is important. La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ (LSCF) is attracting substantial interest as a promising cathode material for LT-SOFCs because of its excellent properties, such as chemical and thermal stabilities, high catalytic activity for the oxygen reduction and high electrical conductivity [3]. LSCF materials may replace the conventional LSM materials [4-7]. LSCF based materials were synthesized by combustion synthesis [8-9], complexing method [10], sol-gel process [11], etc. In the present investigation, we report a simple way synthesizing multicomponent perovskite oxide nanoparticles such as, La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_{3-δ}$, La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-δ}$, La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_{3-δ}$, La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-δ}$ by low temperature chemical precipitation method for possible application as cathode materials in LT-SOFC. The prepared nanoparticles are systematically characterized by TGA, XRD, FTIR, Particle Size analysis and SEM techniques.

**EXPERIMENTAL**

**Materials and methods**

Lanthanum nitrate hexahydrate (La(NO$_3$)$_3$·6H$_2$O, 99%, Loba Chemie), Strontium nitrate (Sr(NO$_3$)$_2$, 99%, Nice), cobalt nitrate non-hydrate (Co(NO$_3$)$_2$·9H$_2$O, ≥97%, Merck), iron nitrate nonahydrate (Fe(NO$_3$)$_3$·9H$_2$O, 98%, Fisher Scientific), Sodium hydroxide (NaOH, ≥97%, Merck) and Poly vinyl alcohol (PVA, 99% Merck) were used as starting materials. Deionized water was used for all the experiments.

**Preparation of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ (LSCF) nano ceramic particles by chemical precipitation method**

In the typical experiment, the aqueous solutions of lanthanum nitrate hexahydrate, strontium nitrate, cobalt nitrate hexahydrate, ferric nitrate nonahydrate [as basic materials] and sodium hydroxide [as precipitator material] were prepared in distilled water. The later solution was mixed 2 ml of 10% poly vinyl alcohol (as surfactant material). Initially, the aqueous metal nitrate solutions were added slowly drop-wise to the sodium hydroxide solution. They were mixed perfectly by a magnetic stirring apparatus (1000rpm) at room temperature for an hour. Throughout the experiment, the pH was maintained as pH≥9 by the addition of alkali. The resultant brown colour precipitate [La(OH)$_3$+Sr(OH)$_2$+Co(OH)$_2$+Fe(OH)$_3$ with PVA] was filtered and then washed with deionized water and ethanol (9:1) for 2 to 3 times and dried at 50–100 °C for 2 to 3 hours. The resultant material was heat treated at 300°C, 450°C, 600°C and 750°C for 2 hours each to get a phase pure product. The amount of precursor materials used for the preparation of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ nanoparticles is indicated in Table 1. Figure 1 shows the schematic illustration of the synthesis of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ nanoparticles by the chemical precipitation method. Main reactions involved in the preparation of La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_{3-δ}$, La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-δ}$, La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_{3-δ}$ and La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-δ}$, that occur during the experimental procedure can be written briefly as follows:

Fig. 1. Schematic representation of the synthesis of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-\delta}$ nanoparticles by chemical precipitation method.
Characterization of the samples

Thermal analysis of the precursor precipitate was performed with Perkin Elmer TGA 7 instrument under nitrogen atmosphere at a heating rate of 10° C /minute. The powder XRD studies were carried out using a Shimadzu XRD6000 X-ray diffractometer at a scan speed of 5 degrees minute⁻¹ using CuKα radiation. The theoretical density of the powders was calculated with the obtained XRD data. The crystallite sizes of the powder were calculated by Scherrer’s formula. Bruker IFS 66V FT-IR spectrometer was employed to record the FTIR spectra of doped CeO₂ powders in the range of 4000 – 400 cm⁻¹. The crystallite sizes of the ceramic powders were calculated by Scherrer’s formula. The particle size of the powder was measured using Malvern Particle Size Analyzer using triple distilled water as medium. The surface morphology of the particles was studied by means of JEOL Model JSM-6360 scanning electron microscope.

RESULTS AND DISCUSSION

TGA studies of precursor materials

The dried precursor precipitate [La(OH)₃+Sr(OH)₂+Co(OH)₂+Fe(OH)₃] with PVA] with an initial mass 5–9 mg was placed in an open platinum crucible. The mass scale of the instrument was calibrated with standard reference materials based on the measurement of curie Points (Tc) of alunel alloy (Tc = 427.35 K) and nickel (Tc = 628.45 K). The TGA patterns obtained with the precursor precipitate materials [La(OH)₃+Sr(OH)₂+Co(OH)₂+Fe(OH)₃] with PVA] are indicated in Figure 2 (a-d). From Figure 2 (a-d), it was understood the total weight loss was found to be in the range of 24 - 31% from the temperature of 25 to 700° C. The initial weight loss of about 2 - 3 % observed at around 100 °C in all the samples may be due to the removal of water molecule. The total weight loss of about 10 – 13 % observed at 300°C in all the samples may be attributed to the removal of oxides of carbon. Further weight loss found in the samples until 700° C may due to the decomposition of remaining organics and other impurities. From the TGA curves of all the samples, it was understood that the weight of the sample reduced gradually from 25 – 700° C. Hence, the TGA results inferred that the resultant precipitate (mixture of hydroxides and surfactant) should be heat treated above 700° C gradually in order to remove the impurities from the sample and to get phase pure material.

Fig. 2. TGA patterns obtained on precursor precipitate material [La(OH)₃+Sr(OH)₂+Co(OH)₂+Fe(OH)₃] with PVA of (a) La₀.₉Sr₀.₁Co₀.₉Fe₀.₁O₃₋δ, (b) La₀.₈Sr₀.₂Co₀.₉Fe₀.₁O₃₋δ, (c) La₀.₉Sr₀.₁Co₀.₈Fe₀.₂O₃₋δ, and (d) La₀.₈Sr₀.₂Co₀.₈Fe₀.₂O₃₋δ.
XRD studies

The powder XRD patterns obtained on La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_3$-$\delta$, La$_{0.8}$Sr$_{0.2}$Co$_{0.9}$Fe$_{0.1}$O$_3$-$\delta$, La$_{0.9}$Sr$_{0.1}$Co$_{0.8}$Fe$_{0.2}$O$_3$-$\delta$ and La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_3$-$\delta$ nanoparticles prepared by chemical precipitation method are indicated in Figure 3 (a–d) respectively. The XRD peaks are found to be very sharp indicating the highly crystalline nature of the perovskite. Since the standard XRD data for La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$-$\delta$ is not available in the literature, the obtained XRD data were compared with the XRD data of standard JCPDS pattern for LaCoO$_3$ (JCPDS card No. 25-1060). The obtained ‘d’ values for LSCF were in match with the reported data for LaCoO$_3$. The XRD patterns of the heat-treated powders reveal the formation of well-crystalline single phase perovskite structure with rhombohedral (hexagonal) cell geometry. The lattice parameters are calculated from 2θ values in the X-ray diffraction patterns and the data is indicated in Table 2. The theoretical density ($D_X$) for the samples was calculated according to the formula [12]:

$$D_X = \frac{Z \times M}{N \times a^3} \text{ g. cm}^3$$

Where, $Z$ = number of chemical species in the unit cell, $M$ = molecular mass of the sample (g/mol), $N$ = Avogadro’s number ($6.022 \times 10^{23}$) and $a$ = lattice constant (cm). Crystallite size of the samples was calculated from XRD line broadening method using the following Scherrer relationship [13]:

$$D_p = \frac{k \lambda}{\beta \cos \theta}$$

Where ‘$D_p$’ is the crystallite size, ‘k’ is a numerical constant (~0.9), ‘$\lambda$’ is the wavelength of X-rays (for CuKα radiation, $\lambda = 1.5418$ Å), ‘$\beta$’ is the effective broadening taken as a full width at half maximum (FWHM) (in radians), ‘$\theta$’ is the diffraction angle for the peak. The crystallographic parameters obtained on La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$-$\delta$ nanoparticles are given in Table 2. The crystallite size values were found in the range of 8.29 – 10.79 nm. The theoretical density values were found to be in the range of 6.8 – 7.1 g/cc.

**FTIR studies**

Figure 4 (a- d) show the FTIR spectra obtained on La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_{3-\delta}$, La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-\delta}$, La$_{0.9}$Sr$_{0.1}$Co$_{0.8}$Fe$_{0.2}$O$_{3-\delta}$ and La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_{3-\delta}$ nanoparticles prepared by chemical precipitation method. The broader peak appeared at ~600 cm$^{-1}$ is characteristic of the MO$_6$ octahedra commonly found in perovskite oxide powder and is observed in this system too [14]. The bands appeared at ~ 600 cm$^{-1}$ and ~650 cm$^{-1}$ in LSCF samples are ascribed to Co-O / Fe-O and BO$_6$ stretch vibrations in the perovskite structure, respectively [15]. The peaks found near to 1600 cm$^{-1}$ in the samples are due to the presence of atmospheric moisture as reported earlier [16].

![Fig. 4. Particle characteristics

The prepared La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$ nanoparticles (after calcination at 750$^\circ$ C for 2 h) were subjected to particle size measurements using Malvern particle size analyzer with triple distilled water as medium. For all the measurements, 0.30 g of sample was sonicated in 30 ml triple distilled water for about 10 minutes and after that the sample was subjected for particle size analysis. The particle size distribution curves of La$_{0.9}$Sr$_{0.1}$Co$_{0.9}$Fe$_{0.1}$O$_3$, La$_{0.8}$Sr$_{0.2}$Co$_{0.9}$Fe$_{0.1}$O$_3$, La$_{0.9}$Sr$_{0.1}$Co$_{0.8}$Fe$_{0.2}$O$_3$, and La$_{0.8}$Sr$_{0.2}$Co$_{0.8}$Fe$_{0.2}$O$_3$ nanoparticles prepared by chemical precipitation method are shown in Figure 5 (a-d). The particle characteristics data obtained on La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$ nanoparticles is indicated in Table 3. The presence of bigger particles (> 500 nm) in the sample may be due to high temperature treatment.

SEM studies

The surface microstructure of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$ nanoparticles was studied with SEM. The SEM photographs of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_3$ nanoparticles are shown in Figure 6 (a-d). SEM analysis provides the information about the size and shape of the particle and pore. From the SEM studies, it was found that the grain size was in the range of 70 – 126 nm. Also, few larger particles are also present in the samples which are in accordance with the particle characteristics data.

CONCLUSIONS

Chemical precipitation method can be effectively used for the preparation of La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ based cathode materials for application in LT-SOFCs. TGA patterns obtained on precursor precipitate revealed the methodology to get phase pure La$_{1-x}$Sr$_x$Co$_{1-y}$Fe$_y$O$_{3-δ}$ materials. The powder XRD data obtained is in agreement with the standard reported JCPDS data and crystallized as rhombohedral (hexagonal) cell geometry. From the FTIR spectra, it is observed that characteristic peak (~650 cm$^{-1}$) is present in all four samples. The presence of nano particles is confirmed by the particle size analysis and SEM measurements.
