Abstract
In the present work, the exact diagonalization method had been implemented to calculate the ground state energy of shallow donor impurity located at finite distance along the growth axis in GaAs/AlGaAs heterostructure in the presence of a magnetic field taken to be along z direction. The impurity binding energy of the ground state had been calculated as a function of confining frequency and magnetic field strength. We found that the ground state donor binding energy (BE) calculated at $\omega = 2.0R^*$ and $B = 5.421R^*$, decreases from $BE=7.59822R^*$ to $BE=2.85165R^*$, as we change the impurity position from $d=0.0a^*$ to $d=0.5a^*$, respectively. In addition, the combined effects of pressure and temperature on the binding energy, as a function of magnetic field strength and impurity position, had been shown using the effective-mass approximation. The numerical results show that the donor impurity binding energy enhances with increasing the pressure while it decreases as the temperature decreases.

Keywords: Binding Energy; Donor Impurity; Exact Diagonalization Method; Heterostructure; Magnetic Field.

INTRODUCTION
Low dimensional heterostructure have been studied intensively in the last decades, both theoretically and experimentally [1-3]. Quantum confined semiconductor systems such as quantum well (QW), quantum well wire (QWW), quantum dots (QD) and quantum rings (QR) are important elements in the present electronic devices. The electrical, optical and transport properties of these semiconductor heterostructure systems can be changed by external effects like: donor impurities near the heterostructure surface, electric field, magnetic field, pressure, and temperature [3,4]. Moreover, the effect of the donor impurity on the properties of the heterostructure materials is very interesting subject which has been investigated. Adding the donor impurity atoms change the effective charge and mass of it, which alter the performance of the quantum devices and the transport properties [5]. The binding energy of the impurity and the coulombic interaction between the system charge carrier and the donor impurity change the heterostructure energy gap [6, 7]. The donor impurity binding energy had been investigated from bulk to the quantum dot where it depends on the dimensionality of the system, shape, and the impurity position [1, 8, 9]. Also, it is affected the heterostructure properties by the presence of the magnetic or electrical fields, pressure, and temperature [9, 10]. For the quantum dot, the donor impurity binding energy increases continuously with decreasing the dot radius, and the applied magnetic field strength, in addition, it depends on the impurity position [11, 12].

The donor binding energy had been studied for the quantum well by using variation method, where the ground state of donor binding energy had been computed as a function of the impurity position and the QW width under different electric...
field strengths [13, 14]. The donor impurity energy for the ground and excited state of two-dimensional heterostructure had been computed as a function of magnetic field strength, for both weak and strong magnetic field limit, using exact and perturbation methods [15]. Chuu et al. in Ref. [16] obtained the donor impurity energy levels analytically for both donor impurity located at the quantum dots center, and for donor impurity located at the axis of the quantum-well wire. Zhu and Gu in Ref. [17] investigated the dependence of the energy transition on shallow donor impurity states in a harmonic QD by using analytical method with the presence of the magnetic field. The energy transition changes with the magnetic field strength, where the result shows the high effects of magnetic fields on donor impurity energy states transition [17]. The dependence of the diamagnetic susceptibility and the binding energy of the donor impurity on the pressure and the temperature had been shown analytically. Khordad and Fathizadeh found in their recent study the diamagnetic susceptibility increases by increasing the pressure and it decreases with increasing the temperature [18]. Peter in Ref. [19] reported the binding energy levels of shallow hydrogenic impurities in a parabolic quantum dot (QD) with pressure effect using variation approach. Where, they are found that the ionization energy, is purely pressure-dependent. Merchancano et al. in Ref. [2] had also calculated the binding energy of the hydrogenic impurities in a spherical QD using the variation and perturbation approaches as a function of pressure, QD size, and the impurity position. The results of the study show that the binding energy increases with increasing the pressure [20]. The combined effects of pressure and temperature on the binding energy of donor impurity in a spherical QD with the presence of the electric field or without had been investigated [5, 21].

The exact diagonalization method had been used to solve the problem of two interacting electrons in the QD including the pressure and temperature effects. The magnetization and magnetic susceptibility of confined electrons in parabolic quantum dot was considered in both: experimental and theoretical studies [22, 23]. Very recently, Elsaid et al. [24-32], has studied the electronic, thermodynamic and magnetic properties of two electrons confined in a single quantum and coupled quantum dots (CQD). Alfonso et al. in [33] had investigated the energy states of an electron confined in a two-dimensional (2D) plane and bound to an off-plane shallow donor center in the presence of an external magnetic field by using variation and numerical approaches. The effect of impurity on energy levels in double quantum rings had been considered by Khajeh Salehani et al. [34].

In this work, we have investigated the combined effects of pressure, temperature, magnetic field strength and the impurity position on the ground state binding energy of the donor impurity in heterostructure materials. We have computed the ground state energy level of donor impurity in a heterostructure by solving the donor impurity Hamiltonian using exact diagonalization method. The Hamiltonian theory of donor impurity located along the growth axis under the effect of a magnetic field, pressure and temperature had been presented, followed by numerical results and discussion. The conclusion is given at the end of the work.

THEORY

This section describes the main parts of the donor impurity formulation: i) the quantum heterostructure Hamiltonian, ii) the exact diagonalization method and iii) the pressure and temperature effects on the computed donor impurity ground state binding energy by the effective-mass approximation. The system is a quantum heterostructure confined in the x-y plane with parabolic confinement potential of confining strength \( \omega_0 \), \( V(r) = \frac{1}{2} m^* \omega_0^2 r^2 \), and in the presence of a donor impurity along the z-axis located at distance \( d \), under the influence of a uniform magnetic field strength, \( B = V \times A \), applied along the \( z \)-direction. \( A = \frac{B}{2} (x, y, x, 0) \) is the vector potential.

The interaction between the electron in the GaAs layer and the donor impurity, located at distance \( d \) along the \( z \)-direction in AlGaAs barrier, is attractive coulomb interaction energy. The Hamiltonian of the donor impurity can be written in an operator form as:

\[
\hat{H} = -\left( \frac{1}{2} m^* \frac{\partial^2}{\partial x^2} + \frac{1}{2} m^* \frac{\partial^2}{\partial y^2} + \frac{1}{4} \omega^2 r^2 + \frac{1}{2} \frac{\omega_0}{m^*} \frac{\partial}{\partial \theta} - \frac{2}{|p| \cdot d} \right) \frac{1}{2}
\]

in Eq. (1) can be separated into two parts as:
\[ \hat{H} = \hat{H}_\perp + V(\rho) \]  
where:
\[ \hat{H}_\perp = -\left( \rho^{-1/2} \frac{\partial^2}{\partial \rho^{1/2}} \rho^{1/2} \right) + \frac{1}{\rho^2} \left( \frac{\partial^2}{\partial \phi^2} \phi + \frac{1}{4} \right) \]
\[ + \frac{1}{4} \omega^2 \rho^2 - i \omega_c \frac{\partial}{\partial \phi} \]  
and,
\[ V(\rho) = \frac{2}{|\rho - d|} = -\frac{2}{\sqrt{\rho^2 + d^2}} \]

The potential \( V(\rho) \) represents the coulomb interaction between the electron in the GaAs layer and the impurity ion, located at distance \( d \) along the z-direction in AlGaAs barrier screened by the dielectric constant of GaAs medium. The Hamiltonian \( \hat{H}_\perp \) is a harmonic oscillator type with well-known solution. The effective confinement frequency, is a combination of the magnetic field cyclotron frequency and parabolic confining frequency, given as: \( \omega_c = \omega_0 + \frac{\omega_e}{2^2} \). Generally, there is no analytical solution available for the complete donor impurity Hamiltonian. In this work, we will use the exact diagonalization technique to solve the donor impurity Hamiltonian given by Eq. (1) and study its electronic properties.

For zero donor impurity case \( \hat{H}_\perp \), Eq. (1) reduces to harmonic oscillator type with a well-known eigenstates \( |n,m> \) and eigenenergies. The adopted basis \( (|n,m> = \psi_{n,m} (\rho, \phi) ) \) are harmonic oscillator type wave functions that have been used to diagonalize the total Hamiltonian and obtain the ground state energy of the impurity system.

![Figure 1a](image1.png)

**Fig. 1.** The ground state energy of the quantum heterostructure for fixed value of magnetic field strength (\( \omega_c = 2 \ R^* \)) and parabolic confining strength (\( \omega_0 = 5.412 \ R^* \)) against the number of basis for a) donor impurity at the origin \( (d = 0 \ a^*) \) and b) donor impurity at \( (d = 0.5 \ a^*) \).
The donor impurity binding energy (BE) which is defined as the difference between the layer and the impurity ion, located at distance \( d \) along the \( z \) -direction in AlGaAs barrier where

\[
\rho_{n,m}(\rho,\phi) = \frac{1}{\sqrt{2n}} R_{n,m}(\rho) e^{im\phi}
\]

and eigen energies

\[
E_{n,m} = (2n + |m| + 1)\hbar\omega + \frac{m^2}{2m^*}
\]

where \( \langle \rho,\phi'\rangle \) is the standard associated Laguerre polynomials [34]. And \( \alpha \) is an inverse length dimension constant which is given by:

\[
\alpha = \sqrt{\frac{m\omega}{\hbar}}
\]

Using these harmonic oscillator bases \( |n,m> \), the matrix elements of the full donor impurity Hamiltonian; \( \langle R_{n,m}(\rho) | H | R_{n,m}(\rho) \rangle \), can be diagonalized numerically to obtain the desired eigenenergies. In each calculation step the number of basis \( |n,m> \) will be varied until a satisfied converging eigenenergies are achieved. The stability converging procedure is displayed in Fig. 1.

The donor impurity binding energy (BE) which is defined as the difference between the energy states of the Hamiltonian (Eq. 1) without the presence of the impurity (\( E \)) and with its presence (\( E_0 \)).

\[
BE = E - E_0
\]

For quantum heterostructure made of GaAs the dielectric constant \( \varepsilon_r(P,T) \) and the electron effective mass \( m^*(P,T) \) are presented by [10]

\[
\varepsilon_r(P,T) = \begin{cases} 
12.74 \exp(-1.73 \times 10^{-3}P) \exp[9.4 \times 10^{-5}(T - 75.6)] & \text{for } T < 200 \text{ K} \\
13.18 \exp(-1.73 \times 10^{-3}P) \exp[20.4 \times 10^{-5}(T - 300)] & \text{for } T \geq 200 \text{ K} 
\end{cases}
\]

\[
m^*(P,T) = \left[ 1 + 7.51 \left( \frac{2}{E_0^\text{g}(P,T)} + \frac{1}{E_0^\text{g}(P,T) + 0.341} \right) \right]^{-1} m_0
\]

\[
E_0^\text{g}(P,T) = \left[ 1.519 - 5.405 \times 10^{-4} \frac{\gamma^2}{T + 204} \right] + bP + cP^2
\]

Where \( m_0 \) is the free electron mass, \( E_0^\text{g}(P,T) \) is the pressure and temperature dependent energy band gap for GaAs quantum heterostructure at \( \Gamma \) point, \( b = 1.26 \times 10^{-1} \text{eV GPa}^{-1} \) and \( c = -3.77 \times 10^{-3} \text{eV GPa}^{-2} \).

The effective Rydberg in term of pressure and temperature is used as the energy unit.

\[
R^\text{f}_{\alpha}(P,T) = \frac{e^2}{2\varepsilon_r(P,T)\alpha^2_{\alpha}(P,T)}
\]

Where \( \alpha^\text{f}(P,T) \) is the effective Bohr radius which given as:

\[
\alpha^\text{f}(P,T) = \frac{\varepsilon_r(P,T)\hbar^2}{m^*(P,T)e^2}
\]

Finally, the effective Rydberg can be written as:

\[
R^\text{f}_{\alpha}(P,T) = \frac{e^4m^*(P,T)}{2(\varepsilon_r(P,T))^2\hbar^2}
\]

Table (1) shows the variation of the material physical parameters, like effective mass and dielectric constant, in terms of the pressure and temperature.

**RESULTS AND DISCUSSIONS**

For heterostructure system made from GaAs the material parameters are: dielectric constant \( \varepsilon = 12.4 \), effective Rydber \( R = 5.926 \text{meV} \) and

Fig. 2. The ground state energy of the quantum heterostructure for absence and presence of the impurity against the magnetic field strength ωc the dashed line with impurity and solid line for no impurity cases for ωc = 5.412 R*.

Fig. 3. The ground-state for fixed value of ωc = 2 R* against the distance for two ωc, (ωc = 3.044 R dashed line and ωc = 5.412 R*) the solid line.
the effective mass of an electron $m^* = 0.067 m_e$ at ambient zero temperature and pressure. The impurity is located along z axis at the distance $d$, with the presence of a uniform external magnetic field $B$ along the z direction. In the first step we have calculated the ground state eigenenergy $(m=0)$ for the donor impurity of GaAs/AlGaAs heterostructure as a function of the...
two specific values of the confinement frequency strength \( \omega_0 \) with impurity located at the origin \((d=0)\) for two specific values of the confinement frequency strength \( \omega_0 = 5.412 \, R^* \), and \( \omega_0 = 3.044 \, R^* \). The accuracy of our obtained results are tested against the corresponding ones produced by \( \frac{1}{N} \) expansion method [35]. Table 2 shows the comparison between the ground state \((m=0)\) computed energy for the present exact diagonalization method and the available corresponding energy produced by \( \frac{1}{N} \) expansion method. The comparison shows a good agreement between both methods. To test the convergence issue of our exact diagonalization technique, we have plotted in Fig. 1a,1b, the computed ground state energies \((E)\) of the donor impurity Hamiltonian against the number of basis \((n)\) from 1 to 38 for frequency \( \omega_0 = 5.412 \, R^* \), impurity distance \(d=0 \, a^*\) and \(0.5 \, a^*\), and at magnetic field strength \( \omega_c = 2 \, R^* \). The figures clearly show the numerical stability in our computed scheme. The ground state approaches a limiting value as the number of basis increases.

Fig. 2 displays the energy of the donor impurity energy as a function of the magnetic field strength \( \omega_c \), for confinement frequency \( \omega_0 = 5.412 \, R^* \). The solid plot of the system indicates the absence of the impurity, and the dashed one indicates the presence of the impurity. It is clear from Fig. 2 that the effect of the impurity is to decrease the energy of the system. The presence of donor impurity lowers the energy of the heterostructure energy due to it negative coulomb attraction.

The energy of the heterostructure shows a significant dependence on the impurity position. Increasing the impurity distance \((d)\), changing the system from 2D to 3D (bulk), as displayed clearly in

Table 3. The donor impurity ground state energy \((E(R^*))\), and donor impurity binding energy \((BE(R^*))\) against the magnetic field strength \( \omega_c \) and various impurity position \((d)\) for \( \omega_0 = 3.044 \, R^* \).

In Table 3, we have listed the donor impurity energy and binding energy as a function of the magnetic field strength increases. This behavior persists for all d-values. However, the binding energy of the donor Hamiltonian enhances as the impurity (d) increases. We can see a significant decrease in the binding energy at constant pressure (P=10 kbar) and for three temperatures (5K, 100K, and 200K) for (a) $\omega_0 = 3.044 \, a^*$ and (b) $\omega_0 = 5.412 \, a^*$.

Furthermore, we have investigated the impurity ground-state eigenenergy ($E$) and the energy of the donor Hamiltonian enhances as the parabolic confinement strength ($R^*$) and the number of impurities against $R^*$ at constant pressure (P=10 kbar) and for three temperatures (5K, 100K, and 200K) for (a) $\omega_0 = 3.044 \, a^*$ and (b) $\omega_0 = 5.412 \, a^*$.

Fig. 3. For fixed values of impurity position (d), the energy of the donor Hamiltonian enhances as the confinement strength ($\omega_0$) increases from 3.044 to 5.412R$. This energy behavior agrees with our expectation. Furthermore, we have investigated the impurity...
This result is due to the great reduction in the coulomb impurity energy (Eq. 4), as we have inserted the pressure and temperature dependent material from 3.044 R* to 5.412R*. This energy behavior agrees with our expectation.

The accuracy of our obtained results are tested against the corresponding ones produced by the expansion method [35]. Table 2 shows the comparison between the ground state (m=0) computed energy for the present exact diagonalization method and two specific values of the confinement frequency strength $\omega_0$.

Furthermore, we have investigated the impurity ground-state eigenenergy (E) and the binding energy (BE) against the magnetic field strength $\omega_c$, for specific values of $\omega_0$ and versus values of (d). Fig. 4a, 4b, 4c, 4d show the dependences of the ground state binding energy (BE) on the magnetic field strength $\omega_c$ for different values of impurity distances : (a) d=0 $a^*$, (b) d=0.1$a^*$, and (c) d=0.5$a^*$ and two confinement frequencies ( $\omega_0 = 3.044 R^*$ and $\omega_0 = 5.412R^*$). The binding energy (BE), against the magnetic field strength, is greatly reduced as the distances (d) increases as shown by Figs. 2, 3 and 4. In addition, the figures demonstrate that the binding energy increases as magnetic field $\omega_c$ and the parabolic confinement strengths $\omega_0$ increase.

In Table 3, we have listed the donor impurity energy and binding energy as a function of magnetic field strength $\omega_c$ for $\omega_0 = 3.044 R^*$ and for various values of d. For $\omega_0 = 3.044 R^*$ and d=0 $a^*$, the binding energy increases as the magnetic field strength increases. This behavior persists for all d-values. However, the binding energy decreases as the impurity (d) increases. We can see a significant decrease in the binding energy as d increases from d=0.1 $a^*$ to d=0.5 $a^*$. For example, at $\omega_0 = 3.044 R^*$ and $\omega_0 = 2 R^*$ the binding energy reduces significantly from 4.62499 $R^*$ to 2.55177 $R^*$. This result is due to the great reduction in the coulomb impurity energy (Eq. 4), as we mentioned earlier. The same qualitative behavior can also be observed in Table 4 with different quantitative behavior for $\omega_0 = 5.412 R^*$.

To see the effects of pressure and temperature parameters on the binding energy of the donor.
impurity, we have inserted the pressure and temperature dependent material parameters of GaAs, \( m^* (P, T) \) and \( \varepsilon_r (P, T) \), in the present calculations. In Fig. 5 to Fig. 16, we have shown explicitly the behavior of the donor binding energy (BE) as a function of the magnetic field strength \( \omega_0 \), taking in consideration the impurity position (d), temperature (T), pressure (P) and confinement frequency \( \omega_0 \). Fig. 5a, 5b show the donor binding energies against the magnetic field strength for three different temperatures (5K, 100K, and 200K) and fixed values of pressure, impurity position \( d=0 \) and confinement frequency \( \omega_0 = 3.044 R^* \). For fixed temperature, the figure clearly shows the enhancement of the binding energy as the magnetic field strength \( \omega_0 \) increases. This enhancement in the donor binding energy can be attributed to the parabolic magnetic confinement term \( \frac{1}{2} m^* \omega^2 p^2 \) in Eq. (3). For fixed values of magnetic field strength \( \omega_0 \), the binding energy decreases when the temperature increases, as clearly shown in Fig. 5a. Similar behavior of the donor binding energy is displayed in Fig. 5b for different, \( \omega_0 = 5.412 R^* \).

In Fig. 6 we have shown the dependence of the donor binding energy on the temperature for fixed values of pressure (\( P=10 \) Kbar), \( \omega_0 = 2 R^* \), \( d = 0 \) and various confinements \( \omega_0 = 3.044 R^* \) \( \omega_0 = 5.412 R^* \). The binding energy again shows a clear decreasing behavior as the temperature of the system increases. The dependence of the material parameters like the effective mass \( m^* (P, T) \) and dielectric constant \( \varepsilon_r (P, T) \) on the temperature and pressure explain in Table 1, where \( m^* \) decreases and \( \varepsilon_r \) increases with increasing T which diminish donor impurity binding energy (BE).

In Fig. 7a, 7b, the behavior of the donor binding energy had been shown as a function of the magnetic field strength \( \omega_0 \) for different values of parameters: \( \omega_0 = 5.412 R^* \) \( \omega_0 = 3.044 R^* \), pressure \( P=0, 10, \) and 20 kbar, impurity position \( d=0 \) \( \omega_0 \), and temperature \( T=20 \) K. The donor binding energy shows a significant increase as the magnetic field \( \omega_0 \) increases; as we increase the magnetic field strength \( \omega_0 \), the electron-atom separation distance decrease which in turn increases the electron confinement. The binding energy again shows a great enhancement as the pressure increases, while keeping the magnetic field strength unchanged.

In Fig. 8, we take the temperature \( T=20K \), \( \omega_0 = 2 R^* \) and \( d = 0 \) parameters, while changing the pressure. We observe a great enhancement in the donor binding energy as the pressure increases for confinement strength: \( \omega_0 = 3.044 R^* \) \( \omega_0 = 5.412 R^* \). This behavior is expected; since as we increase the pressure, the effective mass \( m^* \) increases while the dielectric constant \( \varepsilon_r \) decreases. These changes in the material parameters lead to a reduction in the kinetic energy of the electron while the attractive

![Fig. 8. The variation of ground-state binding energy for \( d = 0 \) against the pressure at fixed temperature (20K) and \( \omega_0 = 2 R^* \) for \( \omega_0 = 3.044 R^* \) and \( \omega_0 = 5.412 R^* \).](image-url)
coulomb energy of the electron enhances.

In Fig. 9a and 9b, we have shown the effect of changing the temperature, at fixed value of the impurity position (d= 0.1 a*), on the binding energy. Again, the binding energy shows great enhancement as we increase the magnetic field strength ωc, for fixed values of the parameters: Temperature (T= 5, 100, and 200K), Pressure (P=10 kbar) and confinement frequencies ω0 = 3.044 R* and ω0 = 5.412 R*. We display in Fig. 10 the donor binding energy against the temperature (T), while the rest of the physical parameters of the system are kept fixed. The binding energy shows an important dependence on the temperature, and the impurity binding energy $E_b$ decreases with increasing the temperature.

In Fig. 11a and 11b, the pressure effect on the donor binding energy for d=0.1 a* against the magnetic field strength ωc had been illustrated. Fig. 11a obviously shows that the binding energy increases as the magnetic field strength enhances while the pressure (0, 10, and 20 kbar), T, d, and ω0 = 3.044 R* are fixed. Fig. 11b shows similar behavior of the (BE) but for different confinement $\omega_0 = 5.412 R^*$. Effective-mass approximation investigates the pressure effects on $m'$ and $\varepsilon_r$, as shown in Table 1 which explain the reason of enhancing BE.
Fig. 10. The ground-state binding energy for d = 0.1 \( \omega^* \) at constant pressure (P=10 kbar and \( \omega_0 = 2 \omega^* \), and temperature for \( \omega_0 = 3.044 \omega^* \) dashed line and \( \omega_0 = 5.412 \omega^* \) for the solid line).

Fig. 11. The variation of binding energy for d=0.1 \( \omega^* \) against the number of \( \omega \), for (a) donor impurity at the origin (d = 0 \( \omega^* \)) and (b) donor impurity at (d = 0.5 \( \omega^* \)) at constant pressure (P=10 kbar) as a function of the pressure \( \omega \) for three temperatures (5K, 100K, and 200K).

Fig. 12. The variation of binding energy for d=0.1 \( \omega^* \) against the pressure at fixed temperature (20K) and for three pressure values (0, 10, and 20 kbar) a) for \( \omega_0 = 3.044 \omega^* \) and (b) \( \omega_0 = 5.412 \omega^* \).
In Fig. 12, the ground state binding energy as a function of the pressure for fixed values of $T=20K$, $d = 0.1 a^*$, $\omega_c = 2 R^*$, and at different confinements: $\omega_0 = 3.044 R^*$ and $\omega_0 = 5.412 R^*$ had been plotted. The binding energy, (BE) shows a great enhancement as the pressure increases for fixed values of confinement frequency because of increasing $m^*$ and decreasing $\epsilon_f$. This effective

![Fig. 12](image-url)
mass and dielectric pressure dependence lead to lower the electron kinetic energy while the coulomb energy increases.

Fig. 13a and 13b, the binding energy as a function of magnetic field strength for d=0.5 $\omega^*$ and various confinement, had been shown. We have plotted in Fig. 14 the dependence of the donor binding energy against the temperature for ( $\omega_0 = 3.044 R^*$ for dashed line and for $\omega_0 = 5.412 R^*$ solid line).

Fig. 15. The binding energy for d=0.5 $\omega^*$ against the temperature for ( $\omega_0 = 3.044 R^*$ for (dashed line and for $\omega_0 = 5.412 R^*$ solid line).
In Table 3, we have listed the donor impurity energy and binding energy as a function of magnetic field strength. In addition, the figures demonstrate that the binding energy increases as magnetic field decreases as the impurity (d) increases. We can see a significant decrease in the binding energy as the magnetic field strength increases. This behavior persists for all d-values. However, the binding energy increases as the magnetic field strength increases. This result is due to the great reduction in the coulomb impurity energy (Eq. 4), as we increase the temperature from T=5K to T= 200 K, respectively calculated at $\omega_0=2.0 R^*$, $\omega_0=5.412 R^*$ and pressure P=10 Kbar. Also the donor impurity binding energy is increasing function of pressure for fixed values of temperature and magnetic field. For strong magnetic field strength, the donor binding energies enhances significantly for any hydrostatic pressure and temperature values as we expected.
